ABSTRACT

Tourism in China is gradually shifting from sightseeing to recreational tourism. The shift calls for transformation and upgrading of tourism products. Therefore, it is critical to rationalize the spatial distribution of tourist resorts. Targeting 30 national tourist resorts in China, this paper systematically analyzes the spatial distribution of these resorts, using nearest neighbor index (NNI), Gini coefficient, and kernel density estimation (KDE). Besides, a spatial regression model was adopted to identify the influencing factors of the spatial distribution. The results show that: China’s national tourist resorts are mainly concentrated in four hotspots in East, Southwest, South, and Central China; the spatial distribution is strongly influenced by the provincial/regional tourism and capital investment, greatly impacted by infrastructure and economy, and slightly affected by government support and ecological awareness; in the future, China should develop more tourist resorts in the northwest, north and northeast, and set up a multi-core spatial distribution and product system.

1. INTRODUCTION

The history of tourist resorts can be traced back to the 1930s in Europe. After the end of the WWII, tourism as a global industry flourished thanks to the boom of world economy and the invention of paid holidays. The tourists, no longer satisfied with sightseeing, went on vacations to improve physical and mental health through rest and relaxation. As a result, tourist resorts have sprung up in developed countries of Europe and North America. Over the years, recreational tourism has created a vibrant visitor economy in these countries. Since the 1960s, the studies on tourist resorts have mainly tackled the following aspects: cycle and development process [1-5], types [6-10], environmental impacts [11-23], relevant stakeholders [14-18], management and marketing [19-21].

By contrast, recreational tourism started late in China. The first tourist resorts in the country were developed in 1992. The relevant research mainly explores on the 12 earliest national tourist resorts, from the angles of planning and design [22], tourist satisfaction [23] and marketing strategy [24]. There is no report on the spatial distribution of national tourist resorts.

To make up for the gap, this paper selects 30 national tourist resorts in China as objects, and analyzes their spatial distribution features (e.g. spatial structure and hotspot), using nearest neighbor index (NNI), Gini coefficient, and kernel density estimation (KDE). Besides, a spatial regression model was adopted to identify the influencing factors of the spatial distribution. The research results lay a scientific basis for the reasonable spatial layout and sustainable development of national tourist resorts in China.

2. OVERVIEW OF TOURIST RESORTS IN CHINA

2.1 History

In China, the development of tourist resorts can be divided into two phases: the exploratory phase from 1992 to 2008, and the present phase since 2009. In 1992, twelve national tourist resorts were established under the approval of the State Council, in a bid to further open up, attract foreign investment and promote tourism. This marks the first attempt of China to develop recreational tourism. Since then, however, no more tourist resort had been approved for a long time.

In 2009, the Opinions of the State Council on Accelerating the Development of the Tourism (the State Council [2009] 41) were issued, calling for “effectively promoting the construction of national tourist resorts”. The Opinions were followed by a series of documents, namely, the national standard Resort Rating (GB/T 26358-2010) and the Measures for the Management of Tourist Resorts on Different Levels (the National Tourism Administration [2015] 81). Hence, national tourist resorts once again become the focus and highlight of tourism development.

Subsequently, even more policies on tourism were rolled out, including The Outline for National Tourism and Leisure (2013-2020), and the Several Opinions of the State Council on Promoting the Reform and Development of Tourism (the State Council [2014] 31). In 2015, the National Tourism Administration started a new round of evaluation of tourist resorts, aiming to promote the transformation and upgrading of tourism products and satisfy the demand of recreational tourism at home and abroad.
As of December 2019, there are 30 national tourist resorts and 456 provincial tourist resorts across China. In 2018, the 30 national tourist resorts received a total of 96.6754 million tourists, creating a revenue of 62.686 billion yuan. These tourist resorts set a benchmark for all-for-one tourism and excellent travel experience.

2.2 Classification of tourist resorts

According to Resort Rating (GB/T 26358-2010), the natural resources of tourist resorts fall into seven categories: ocean, inland lakes, mountains, ski resorts, forests, hot springs, and grasslands; the human resources of tourist resorts can be divided into five classes: rural areas, traditional settlements, themed sports (i.e. golf and other themed sports in artificial environment), themed entertainment (e.g. horse racing, film cities, and theme parks), and human activities (i.e. traditional customs and intangible heritage with human as the medium).

Considering their main resources and core attractions, the national tourist resorts in China were classified as Figure 1 and Table 1. The classification results show that China’s national tourist resorts belong to seven types. The top four types are inland lakes (9 tourist resorts, 30%), hot springs (5 tourist resorts, 20%), mountains (6 tourist resorts, 16.67%) and ocean (4, 13.33%).

Figure 1. Distribution of different types of national tourist resorts in China

3. SPATIAL DISTRIBUTION

The vector map data were collected from National Geomatics Center of China (NGCC). The point, line and area layers were all projected in the GCS_WGS_1984 Coordinate system. The latitudes and longitudes were obtained by Google Earth, creating a database of geospatial attributes. The spatial distribution maps of national tourist resorts were generated on ArcGIS 10.2.
3.1 Provincial, regional and altitude distributions

As shown in Figure 2, the national tourist resorts of China are distributed across 18 provincial administrative regions (hereinafter referred to as provinces). Among them, Jiangsu and Zhejiang have the largest number (4), followed by Shandong (3) and Yunnan (3), Guangdong (2) and Sichuan (2), and Chongqing (1), Jilin (1), Anhui (1), Fujian (1), Jiangxi (1), Henan (1), Hubei (1), Hunan (1), Guizhou (1), Hainan (1), Guangxi (1) and Tibet (1). There is no national tourist resort in any of the other 16 provinces.

In terms of geographical regions [25], the national tourist resorts in China are distributed in East China, Southwest China, South China, Central China, and Northeast China. East China has the most national tourist resorts (14), and Northeast China has the fewest (1). No national tourist resort exists in Northwest China and North China (Table 2).

</tbody>
</table>

(Note: Geographically, China can be divided into Northeast China, North China, East China, Central China, South China, Southwest China and Northwest China).

Based on altitude (Figure 3), the national tourist resorts in China are mostly distributed on the second and third steps. On the second step, 7 national tourist resorts dot Sichuan Basin, Eastern Yunnan Plateau and Hubei-Chongqing-Hunan Mountains; on the third step, 22 national tourist resorts are located in Changbai Mountains, Funiu Mountains, Nanyang Basin, Yangtze-Huai River Plain, Yangtze River Delta Plain, Dongting Lake Plain, Pearl River Delta Plain, Lingnan Hills and Southeastern Hills. Overall, the national tourist resorts are scattered in hills and mountains, and concentrated in plains and basins.

![Figure 3. Altitude distribution of national tourist resorts](image)

3.2 Spatial structure

The spatial structure of national tourist resorts in China was analyzed by NNI, Gini coefficient and spatial Lorentz curve. The NNI refers to the mutual proximity of point-like elements in a specific space. The mean nearest neighbor distance (NND) \( r \) of a space equals the average of the NNDs of all points in that space. If the points are randomly distributed, the NND is the theoretical NND \( r \) [26-28]:

![Diagram showing spatial structure](image)
where, \( A \) is the area of the space; \( n \) and \( D \) are the number and density of national tourist resorts respectively. The NNI \( R \) is the ratio of the mean NND to the theoretical NND:

\[
R = \frac{\bar{r}}{r_E}
\]

If \( R > 1 \), the point elements tend to be uniformly distributed; if \( R = 1 \), the point elements tend to be randomly distributed; if \( R < 1 \), the point elements tend to be concentrated in local areas.

Here, national tourist resorts are abstracted as point-like elements, and the NNI is calculated on ArcGIS 10.2. The straight-line distance between two points was computed as Euclidean distance. Through the calculation, the mean NND \( \bar{r} \) was 174.85 km, the theoretical NND \( r_E \) was 225.15 km, and the NNI \( R = 0.776593 < 1 \). The results show that national tourist resorts in China are concentrated in local areas.

The Gini coefficient is often used to measure the distribution difference and change law of point-like elements in the geographic space. The measurement is more contrastive and convincing by the comparison with distribution average degree from Lorentz curve of space [29]. The Gini coefficient \( G_{ini} \) can be defined as:

\[
H = \frac{1}{N} \sum_{i=1}^{N} p_i \ln p_i
\]

\[
H_a = \ln N \quad G_{ini} = \frac{H}{H_a}
\]

\[
C = 1 - G_{ini}
\]

where, \( C \) is the distribution uniformity; \( P_i \) is the percentage of the number of national tourist resorts in a province/region out of the total number of national tourist resorts; \( N \) is the number of regions. The \( G_{ini} \in [0, 1] \) is positively correlated with concentration, and negatively with \( C \).

On the provincial level, it can be calculated that \( G_{ini} = 0.7712 \) and \( C = 0.2288 \). Hence, national tourist resorts are concentrated in local areas, and non-uniformly distributed. The provincial Lorenz curves (Figure 4) indicate that most (60%) national tourist resorts belong to Jiangsu, Zhejiang, Shandong, Yunnan, Guangdong and Sichuan. Thus, the distribution of national tourist resorts in China is extremely unbalanced.

![Figure 4. Provincial Lorenz curves of national tourist resorts in China](image1)

On the regional level, it can be calculated that \( G_{ini} = 0.6786 \) and \( C = 0.3214 \), indicating that national tourist resorts are concentrated in local areas, and non-uniformly distributed. The regional Lorenz curves (Figure 5) reveal that most (73.33%) national tourist resorts are concentrated in East and Southwest China, while none exists in North and Northwest China. There is a great regional difference in the distribution of national tourist resorts.

![Figure 5. Regional Lorenz curves of national tourist resorts in China](image2)
3.3 Hotspots of spatial distribution

The KDE was selected to determine the hotspots in the spatial distribution of China’s national tourist resorts. The KDE algorithm can automatically search for the hotspots of event distribution, and measure the change of event density based on complex distance attenuation. The geographic information system (GIS)-based KDE mainly computes and outputs the point or linear density of each grid with the aid of a moving window. This method visually displays the point elements on a map, and then identifies the hotspot of point distribution in the space. Events are more likely to occur in an area with a high point density, and such an area tends to have a dark color.

Let \( x_1, x_2, ..., x_n \) be independent and identically distributed samples extracted from the distribution density function as a population. Then, the Parzen–Rosenblatt kernel density \( f_n(x) \) at point \( x \) can be expressed as [30]:

\[
 f_n(x) = \frac{1}{nh} \sum_{i=1}^{n} k \left( \frac{x - x_i}{h} \right)
\]

(4)

According to the kernel densities (Figure 6), there are four hotspots in the spatial distribution of national tourist resorts in China: the Yangtze River Delta (northern Zhejiang and southern Jiangsu) in East China, the minority settlement area in South China (central Yunnan), the Yellow River Delta (Jiaodong peninsula) in East China, and the Pearl River Delta (central Guangdong) in South China.

---

4. INFLUENCING FACTORS OF SPATIAL DISTRIBUTION

4.1 Background

There are two distinct features of the spatial distribution of national tourist resorts in China.

(1) National tourist resorts are concentrated in local areas, showing an extremely unbalanced distribution. From the provincial perspective, 60% of all national tourist resorts belong to only six provinces. Jiangsu and Zhejiang boast the largest concentration of national tourist resorts. There is no national tourist resort in economically developed provinces like Beijing and Shanghai, not to mention other provinces like Tianjin, Hebei, Shanxi, Liaoning, Heilongjiang, Shaanxi, Gansu, Qinghai, Inner Mongolia, Ningxia, and Xinjiang. From the regional perspective, 73.33% of national tourist resorts are concentrated in East and Southwest China, while only a few exist in western and northern regions.

(2) There is a dislocation between national tourist resorts and regional resources. China is generally a mountainous country. Most mountains are located in West and Central China. However, mountain tourist resorts are concentrated in East China, and mixed tourist resorts are distributed in South China (Guizhou and Guangxi). Besides, most hot springs in China lie in South China (Fujian and Guangdong) and Southwest China (Sichuan and Tibet), but hot spring tourist resorts are mainly situated in Central China. Despite a 18,000km-long coastline, ocean tourist resorts in China appear at the two ends of the coastline (Shandong Peninsula and Hainan Island).

Globally speaking, the dominant types of tourist resorts are ski resorts and oceanic (Mediterranean coast, Caribbean coast, Southeast Asia and South Asia). By contrast, most national tourist resorts in China belong to the category of inland lakes.

Therefore, regional resources are not the only consideration before setting up a national tourist resorts in China. It is very meaningful to check if the spatial distribution of national tourist resorts is correlated with other factors (e.g. terrain, economy, infrastructure, tourism, and government support), and evaluate the degree of correlation.

4.2 Analysis on influencing factors

4.2.1 Modelling

Multiple regression was adopted to identify the factors affecting the provincial/regional proportion of national tourist resorts and their contributions. The traditional regression model overlooks the correlation effect between units. To improve the fitting results, the spatial effect was introduced to the traditional econometric model. The popular spatial econometric models include spatial lag model (SLM) and...
spatial error model (SEM).

The SLM, also known as spatial autoregressive model, can be expressed as:

$$y = \rho W y + X \beta + \varepsilon$$  \hspace{1cm} (5)

where, $y$ is the dependent variable; $X$ is the independent variable; $\rho$ is the spatial regression coefficient, which measures the degree of spatial interaction between observations; $\beta$ is the parameter vector; $W$ is the spatial weight matrix constructed by the adjacency principle; $\varepsilon$ is the white noise.

The SEM mainly measures the impact of random errors from other units on the observations:

$$y = X \beta + \varepsilon; \quad \varepsilon = \lambda \beta + \mu$$  \hspace{1cm} (6)

where, $\varepsilon$ is regression residual vector; $W$ is the spatial weight matrix constructed by the adjacency principle; $\lambda$ is the autoregressive coefficient to measure the spatial dependence of observations.

4.2.2 Variable selection

In this paper, the provincial/regional proportion of national touri

<td>0.254(0.0120)</td>
</tr>
</tbody>
</table>

Note: The bracketed values are p-values; ***, ** and * are the significance levels of 1%, 5% and 10%, respectively.

Second, provincial/regional infrastructure and economy exert relatively high influence on the spatial distribution of national tourist resorts in China. The regression coefficients of the two factors were 0.877 and 0.859, both passing the 1% significance level. The development of national tourist resorts relies on the tourists with high per capita consumption. The provinces/regions with convenient infrastructure (e.g. transport facilities) and high per capita disposable income could provide a large group of potential consumers. That is why about 2/3 of all national tourist resorts are in economically developed city clusters, such as the Yangtze River Delta city cluster, the Shandong Peninsula city cluster, the central Guizhou city cluster, and the central Yunnan city cluster.

Third, government support and ecological awareness have a certain impact on the spatial distribution of national tourist resorts in China.

Fourth, the landform has little to do with the spatial distribution of national tourist resorts in China.

5. SUGGESTIONS

5.1 Develop more national tourist resorts in Northwest, North and Northeast China

There is a common law in tourism: the area of recreational tourism will dawn, once the per capita GDP surpasses 3,000 USD. In 2018, China was standing on the threshold to that era, as the per capita GDP reached 9,732 USD (64,644 RMB). Thus, it is imperative to optimize the spatial distribution of national tourist resorts.
national tourist resorts, and satisfy the new demand of tourists.

Our research shows the imbalance in the spatial distribution of China’s national tourist resorts. To catch up with other regions, more national tourist resorts should be developed in Northwest, North and Northeast China. These regions enjoy excellent resources like grasslands, ethnic customs, as well as ice and snow. These resources should be fully utilized by attracting tourism capital, improving infrastructure, and stepping up government support. The national tourist resorts in these regions should be developed in synergy with national strategies, such as the Silk Road Economic Belt, the coordinated development of Beijing-Tianjin-Hebei region, and the All-around rejuvenation of Northeast China.

5.2 Construct a multi-core spatial distribution and product system

China has been operating national tourist resorts for 17 years. However, there is not yet a well-connected spatial network of national tourist resorts. The existing national tourist resorts cannot fully demonstrate the provincial/regional features of vacation resources. For instance, there are only 6 mountain tourist resorts and 4 oceanic tourist resorts, although 43% of the country is covered by mountains and over 11,000 islands are off the 18,000km-long coastline. Many mountains and islands have not been well utilized. Similarly, China only has two themed entertainment tourist resorts, and two traditional settlement tourist resorts.

In the future, different provinces/regions should strengthen cooperation and exchanges, and cultivate tourist resorts around city clusters with high per capita GDP and active cooperation and exchanges, and cultivate tourist resorts around city clusters with high per capita GDP and active cooperation and exchanges, and cultivate tourist resorts around city clusters with high per capita GDP and active cooperation and exchanges, and cultivate tourist resorts around city clusters with high per capita GDP and active cooperation and exchanges, and cultivate tourist resorts around city clusters with high per capita GDP and active cooperation and exchanges, and cultivate tourist resorts around city clusters with high per capita GDP and active cooperation and exchanges.

The possible themes of the future resorts include ski resorts, rural areas, traditional settlements, themed sports, study travel and camping.

6. CONCLUSIONS

The spatial distribution of national tourist resorts in China is critical to the design of the future supply system for recreational tourism. Our research shows that China’s national tourist resorts have developed through two phases. Most of them belong to categories like inland lakes, mountains, hot springs and ocean. These resorts are mainly concentrated in four hotspots in East, Southwest, South, and Central China. The spatial distribution is greatly affected by the provincial/regional tourism, capital investment and other factors. The research results lay a scientific basis for the reasonable spatial layout and sustainable development of national tourist resorts in China.
