ABSTRACT

The effects of temperature dependent viscosity and thermal conductivity on magneto hydrodynamic flow, heat and mass transfer of an incompressible micropolar fluid past an accelerated infinite vertical plate are studied where the viscosity and thermal conductivity are assumed to be inverse linear functions of temperature. The partial differential equations governing the flow, heat and mass transfer of the problem are transformed into dimensionless form of ordinary differential equations by using similarity substitutions. The governing boundary value problems are then solved numerically using shooting method. The effects of various parameters viz. viscosity parameter, thermal conductivity parameter, mass transfer parameter, coupling constant parameter, Prandtl number, Schmidt number, Reynolds number and magnetic parameter on velocity, micro-rotation, temperature and concentration fields are obtained and presented graphically. The Skin-friction, Nusselt number and Sherwood number are also computed and presented in tabular form.

Keywords: Micropolar fluid, Variable viscosity and thermal conductivity, Mass transfer, MHD Flow.

1. INTRODUCTION

The theory of micropolar fluid has been a field of very active research for the last few decades. This theory, first introduced and formulated by Eringen [4] (1966), is capable to explain the complex fluids behaviour such as liquid crystals, polymeric suspensions, animal blood etc. by taking into account the effect arising from local structure and micro-motions of the fluid elements. In the theory of micropolar fluid, each particle has a finite size and constitutes a micro structure, which can rotate. This local rotation of the particles is in addition to the usual rigid body motion of the entire volume element. The effect of magneto hydrodynamics on micropolar flow has become important due to several engineering applications such as in MHD generators, designing cooling system for nuclear reactor, flow meters etc., where the micro concentration provides an important parameter for deciding the rate of heat flow. Several investigators have made theoretical and experimental studies of micropolar flow in the presence of a transverse magnetic field during the last decades. Assuming fluid viscosity as a linear function of temperature the effect of variable viscosity on MHD natural convection in micropolar fluids was studied by Abd El-Hakiem et al. [1]. Ahmed and Kalita [2] studied MHD oscillatory free convective flow past a vertical plate in slip- flow regime with variable suction and periodic plate temperature. MHD free and forced convection and mass transfer flow past a porous vertical plate was investigated by Ahmed and Hazarika [3]. Gorla et al. [5] investigated the magneto hydrodynamic free convection boundary layer flow of a thermomicropolar fluid over a vertical plate.

2. OBJECTIVE

The main objective of the present work is to extend the work of Sarma and Hazarika [10] for the study of the effects of variable viscosity and thermal conductivity on the MHD flow of micropolar fluid past an accelerated infinite vertical insulated plate. Viscosity and thermal conductivity are assumed to be inverse linear functions of temperature. The governing partial differential equations are reduced in to ordinary differential equations by using similarity substitutions. The problem is then solved numerically using Runge-Kutta shooting algorithm.

3. MATHEMATICAL FORMULATION OF THE PROBLEM

The general equations of fluid motion for two dimensional unsteady flows in Cartesian co-ordinate are considered
with x-axis along the vertical plate in the upward direction and the y-axis normal to it, where the fluid properties, viscosity, thermal conductivity, and concentration are assumed to vary with temperature. At time $t > 0$ the infinite plate starts moving with a velocity $u = c_0 t$ (where $c_0$ is a positive constant with the dimension of acceleration). As the velocity of the fluid is low, so the viscous dissipative heat is neglected. Also a magnetic field of constant intensity is assumed to be applied normal to the vertical plate and the electrical conductivity of the fluid is assumed to be so small that the induced magnetic field can be neglected in comparison to the applied magnetic field. The applied magnetic field is primary in the $x-y$ plane. Under these assumptions the governing equations of the problem are considered as follows:

3.1 Governing equations

Momentum equation:

$$\frac{\partial u}{\partial t} = g_0 \beta(T - T_\infty) + g_0 \beta^* (C - C_\infty) + \frac{\partial}{\partial y} \left( \nu \frac{\partial u}{\partial y} \right) + \frac{\kappa}{\rho} \left( \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial y^2} \right) - \frac{\sigma_0^2}{\rho} u$$  

(1)

Angular momentum equation:

$$\frac{\partial w}{\partial t} = \frac{\gamma u}{\rho} \frac{\partial}{\partial y} \left( \lambda \frac{\partial}{\partial y} \right)$$  

(2)

Energy equation:

$$\frac{\partial \theta}{\partial t} = \frac{\gamma}{\rho c_p} \frac{\partial}{\partial y} \left( \lambda \frac{\partial \theta}{\partial y} \right)$$  

(3)

Species continuity equation:

$$\frac{\partial a}{\partial t} = \frac{1}{S_e} \frac{\partial}{\partial y} \left( \frac{\partial a}{\partial y} \right)$$  

(4)

3.2 Boundary conditions

The appropriate boundary conditions are:

$$u(0, t) = 0, T(0, t) = T_w, C(0, t) = C_w, N(0, t) = 0, \text{ for } t > 0 \quad \text{and} \quad u(\infty, t) = 0, T(\infty, t) = 0, C(\infty, t) = 0, N(\infty, t) = 0 \quad \text{for } t > 0$$  

(5)

The equation of continuity being identically satisfied by $(u(y, t), 0)$. Following Gurum [6] we assume that $\gamma = \left( \mu_\infty + \frac{k}{\mu_\infty} \right) \frac{j}{\mu_\infty} = 1 + \frac{k}{\mu_\infty} j$, where $K_1 = \frac{k}{\nu_0 \mu_\infty}$, coupling constant parameter.

Following Lai and Kulacki [7] we assume that the viscosity and thermal conductivity are inverse linear functions of temperature, i.e.

$$\frac{1}{\mu} = \frac{1}{\mu_\infty} \left[ 1 + \delta(T - T_\infty) \right], \text{ or } \frac{1}{\mu} = a(T - T_\infty)$$

where $a = \delta \mu_\infty$ and $T_\infty = T_\infty - \frac{1}{\delta}$

Here $a, b, T_c$ and $T_\infty$ are constants and their values depend on the reference state and thermal properties of the fluid i.e. $\nu$ and $\lambda$. In general $a, b > 0$ for liquids and $a, b < 0$ for gases.

We introduce the following similarity transformations:

$$\eta = y \left( \frac{a^2 U_0}{(1 - \alpha t)} \right)^{1/2} \beta(\eta),$$

$$u = U_0 (1 - \alpha t)^{1/2} \beta(\eta),$$

$$N = \sqrt{\frac{U_0}{\nu \alpha}}(1 - \alpha t)i(\eta),$$

$$B = \sqrt{\frac{\alpha U_0}{c_0 (1 - \alpha t)}} B_0,$$

$$C = \frac{c_0 (C_w - C_\infty)}{a U_0} (1 - \alpha t)^{1/2} \beta(\theta),$$

$$T = T_w + \frac{c_0 (T_w - T_\infty)}{a U_0} (1 - \alpha t)^{1/2} \beta(\theta),$$

$$G_r = \frac{g_0 \beta (T_w - T_\infty) c_2 (1 - \alpha t)^{1/2}}{U_0^2 \alpha^3}, \quad G_c = \frac{g_0 \beta^* (C_w - C_\infty) c_2 (1 - \alpha t)^{1/2}}{U_0^2 \alpha^3}$$

Introducing the above transformations in equations (1)–(4), we have the following non dimensional ordinary differential equations

$$\left( 1 + K_1 \frac{\partial}{\partial \theta} \right) f'' = \left[ G_r \theta + G_c \gamma + K_1 \gamma - Mf - \frac{1}{2} K_2 R_e \left( f - \eta f' \right) \right] \frac{\partial}{\partial \theta} + \frac{\partial}{\partial \theta}$$

(6)

$$\left( 2 + K_1 \right) \eta \eta''' = K_2 R_e \left( \eta' \right) \eta + K_1 \left( 4 \eta + 2 f' \right)$$

(7)

$$\theta''' = \frac{1}{2} K_2 P_e \left( \theta - \eta \theta \right) \frac{\partial}{\partial \theta} + \frac{\partial}{\partial \theta}$$

(8)

$$g'' = \frac{1}{2} K_2 P_m \left( g - \eta g \right) \frac{\partial}{\partial \theta} + \frac{\partial}{\partial \theta}$$

(9)

The boundary conditions (5) become

As $\eta = 0$: $f = 0$, $g = 1$, $\theta = 1$, $h = 0$

As $\eta \to \infty$: $f = 0$, $g = 0$, $\theta = 0$, $h = 0$

(10)

The physical quantities of interest in this problem are the skin-friction coefficient $c_f$, Nusselt number $Nu$ and Sherwood number $S_h$ which indicate physically wall shear stress, rate of heat transfer and rate of mass transfer.
respectively. For micropolar boundary layer flow, the wall shear stress \( \tau_w \) is given by

\[
\tau_w = \left[ (\mu + k) \frac{\partial u}{\partial y} + kN \right]_{y=0}
\]

\[
= \rho_v \left( \frac{\theta_e}{\theta_e - 1} + K_1 \right) \frac{\left( \frac{\nu_0}{\nu_0 c_0} \frac{3 \alpha^2}{\nu_0 c_0} f'(0) \right)}{y=0}
\]

The skin-friction coefficient \( c_f \) can be defined as

\[
c_f = \frac{2 \tau_w}{\rho_v u_0^2} = 2 \left( \frac{\theta_e}{\theta_e - 1} + K_1 \right) Re \frac{2}{3} f'(0)
\]

The heat transfer from the plate is given by

\[
q_w = -\lambda \frac{\partial \theta}{\partial y} = \lambda_\infty \frac{\theta_e}{\theta_e - 1} \frac{u_0 c_0}{\nu_0 \alpha^2} \frac{(T_w - T_\infty)}{\nu_0} \theta'(0)
\]

The Nusselt number is given by

\[
Nu = \frac{q_w u_0}{\lambda_\infty (T_w - T_\infty) \alpha} = \frac{\theta_e}{\theta_e - 1} Re \frac{2}{3} \theta'(0)
\]

The mass flux at the wall is given by

\[
M_w = -D \frac{\partial \rho c}{\partial y} = - \frac{v}{\nu_0 c_0} \frac{u_0 c_0}{\nu_0 \alpha^2} \frac{(c_m - c_\infty) \alpha}{\nu_0} g'(0)
\]

\[
S_h = \frac{S c M_w u_0}{\nu_0 (c_m - c_\infty) \alpha} = \frac{\theta_e}{\theta_e - 1} Re \frac{1}{3} \theta g'(0)
\]

4. RESULTS AND DISCUSSION

4.1 Discussion

The equations (6)-(9) together with the boundary conditions (10) are solved for various combinations of the parameters involved in the equations using an algorithm based on the shooting method and results are displayed in the form graph for the dimensionless velocity distribution, dimensionless micro-rotation distribution, dimensionless species concentration distribution, dimensionless temperature distribution with the variation of different parameters.

The values of different parameters have been taken as \( R_e = 0.10, G_e = 0.10, G_c = 0.10, M = 1, Pr = 0.70, Sc = 1, K_1 = 0.10, K_2 = 0.10 \) with the viscosity parameter \( \theta_c \) ranging from -10 to -1 at certain value of \( \theta_e = -10 \) unless otherwise stated. Similarly solutions have been found with the thermal conductivity parameter \( \theta_r \), ranging from -15.00 to -1.00 at certain value of \( \theta_e = -10.00 \) keeping the other values remaining same. Solutions have also been found for different values of magnetic parameter \( (M) \), Prandtl number \( (Pr) \), Reynolds number \( (R_e) \), coupling constant parameter \( (K_1) \) and Schmidt number \( (Sc) \). The variations in velocity distribution, micro-rotation distribution, species concentration distribution and temperature distribution are illustrated in figures (1)-(14) with the variation of different parameters.

The figures (1)—(6) represent the variations in dimensionless velocity distribution with the variation of dimensionless reference temperature corresponding to thermal conductivity parameter \( \theta_e \), Reynolds number \( R_e \), the coupling constant parameter \( K_1 \), magnetic parameter \( M \) and Schmidt number \( Sc \). From figure (1) it is clear that velocity increases with the increasing values \( \theta_c \). This is due to the fact that when the temperature increases viscosity decreases and therefore velocity increases. From figure (2) it is observed that velocity decreases with the increasing values of \( \theta_r \). It is due to the reason that temperature decreases with the increasing values of thermal conductivity and as a result viscosity increases and velocity decreases. Figure (3) represents the distribution of velocity with the variation of Reynolds number \( R_e \). For small values of \( R_e \), viscous force is predominant to inertia force and for increasing values of \( R_e \), viscous force will be decreasing and as a result velocity increases. From figure (4) it is found that velocity decreases with increasing value of coupling constant parameter \( K_1 \). For increasing values of this parameter vortex viscosity increases and therefore velocity decreases. From figure (5) we have observed that velocity decreases with the increasing value of magnetic parameter \( M \). It is due to the fact that the application of transverse magnetic field will result a resistive force (Lorentz force) similar to drag force, which tends to resist the fluid flow and thus reducing its velocity. It is also observed that the velocity is maximum near the plate and decreases away from the plate and finally takes asymptotic value. As the viscosity increases with the increasing values of Schmidt number, from figure (6) we have observed that velocity decreases with the increasing values of Schmidt number.

Figures (7)—(10) display the distributions representing micro-rotation within the boundary layer with the variation of \( \theta_e, \theta_r, K_1 \), and \( M \). From these figures we have observed that the micro-rotation near the surface increases for increasing values of the different parameters and then decreases gradually. It is to be observed that at certain point the parameters have no effect on the micro-rotation distribution. The effect of the Hartmann number \( M \) on micro-rotation is shown in the figure (10). The values of micro-rotation are negative in the first half whereas in the second half these are positive, thus showing a reverse rotation nears the boundary. An increase in magnetic field leads to a decrease in micro-rotation.

Figures (11) and (12) display the variations of dimensionless temperature profile \( \theta(\eta) \) with the variation of dimensionless reference temperature corresponding to thermal conductivity parameter \( \theta_e \), Prandtl number \( Pr \). From figure (11) we have observed that temperature decreases when \( \theta_e \) increases. It is due to the fact that the kinematic viscosity of the fluid increases with the increase of \( \theta_e \) and as a result temperature decreases. It is observed from the figure (12) that temperature increases with the increasing values of \( Pr \). It is due to the reason that with the increasing values of the Prandtl number the thermal diffusivity of the fluid decreases and as a result thermal conductivity decreases. Therefore, the volumetric heat capacity of the fluid becomes larger.

Figures (13) and (14) display the distributions representing concentration profile within the boundary layer with the variation of \( S_c \) and \( R_e \). It is observed that concentration increases with the increasing values of \( S_c \) and \( R_e \). With the increasing value of \( Sc \) mass diffusivity decreases and as a result concentration increases.

Finally, effects of the above mentioned parameters on the values of \( f'(0) \), \( g'(0) \), \( h'(0) \), \( \theta'(0) \), \( c_f \), \( Nu \) and \( S_h \) are shown in the tables (1)—(4). The behaviours of these parameters are self-evident from the tables and hence any further discussions about them are seemed to be redundant.

### 5. CONCLUSION

In this study, the effects of variable viscosity and thermal conductivity on the flow with heat and mass transfer of an incompressible micropolar fluid past an accelerated infinite vertical insulated plate are examined. The results demonstrate clearly that the viscosity and thermal conductivity parameters along with the other parameters such as \( K_T, Sc, Re, M \) and \( P_r \), have significant effects on velocity, temperature, concentration and micro-rotation distributions within the boundary layer. Thus presence of microconstituents may cause a significant change in flow problem.
