Keywords:

GESTOSIS score, machine learning, prediction, pregnancy induced hypertension

This GESTOSIS scale is a validated tool which aids in predicting high risk women for Pregnancy-Induced Hypertension (PIH). This study aimed to use machine learning algorithms to determine the efficacy of the GESTOSIS score in predicting PIH. A prospective observational study was conducted on 70 pregnant women. The features in GESTOSIS scale classified as mild, moderate, or severe. The results showed that the Adaptive Boosting (AB) model precisely predicts the PIH with an accuracy range between 97% to 99% based on the results of regression and classification prediction models respectively with a true -positive rate (TPR) of 90%. The GESTOSIS score is concluded to be a simple scale that can be administered by all front-line health workers in the community without intrusive procedures.

1. INTRODUCTION

Hypertensive disorders in pregnancy are identified after the 20 weeks of gestation, impacting multi-systems within the body. The diagnostic criteria include raised blood pressure to the extent of 140/90 mmHg, high albumin levels, and pathological edema [1]. Pregnancy Induced Hypertension leads to many complications such as preeclampsia, eclampsia, HELLP syndrome, renal and liver failure, retinal detachment, cardiac disorders, and pulmonary edema [2]. If preeclampsia is not treated on time, it leads to the complication of eclampsia, which is the leading cause of maternal mortality and morbidity. Approximately 19 % of deaths are occurring due to PIH among all maternal deaths (WHO 2014) [1], irrespective of mothers espousing health-seeking behaviors to obtain relevant health care services from health care centers/healthcare professionals [3, 4].

According to the short-term statistics of the National Eclampsia Registry (NER 2013), FOGSI, ICOG, prevalence of pre-eclampsia, and eclampsia are 10.3% and 1.9%, respectively. Approximately 50% of these cases [5] are found during antepartum, while 13% of patients are reported in postpartum. About 4-6% of maternal deaths occur due to eclampsia. The causes of maternal mortality [6] in PIH are as follows; 1) Myths and misapprehensions of family members regarding pregnancy, 2) Poor socio-economic status that privations to proper medical care during pregnancy. 3) Lack of transportation facilities to commute the patient to the health care centers in case of any emergency. 4) Lack of medical professionals, i.e., multidisciplinary medical team at community centres and 5) Lack of PIH predictive tools [7].

The universal existing screening tests direct the prediction of PIH. However, most of them are invasive procedures and can be administered only by a physician/ medical officers, and they cannot be administered by all grass-root level health care

professionals such as nursing officers/ ANMs, etc. In India, approximately 70% of the population [8] lives in rural communities. Thus, it is important to develop a simple scale to predict the PIH that all healthcare professionals can administer; therefore, early identification, referral, and proper care can be reached for indigent antenatal women. Preeclampsia prediction aids [1] in the prevention of perinatal and neonatal morbidity and mortality [9, 10]. Preterm birth is common in women with preeclampsia. Preterm newborns who were admitted to NICU significantly contribute to neonatal deaths at 95% confidence interval; however, aspirin administration beginning in the 11th week of pregnancy can reduce complications such as preterm deliveries, neonatal deaths, and maternal deaths [11].

Mandrupkar and team of FOGSI-GESTOSIS-ICOG developed the GESTOSIS score [12]. It helps to categorize the risk factors of pre-eclampsia and design predictive practices and preventive dealings. These methodologies allow the clinician to plan and provide systematic care in pregnancy to prevent eclampsia and other complications by adopting certain standardized clinical management protocols.

1.1 Machine learning algorithms' role in the prediction of preeclampsia

Because of the increasing development of artificial intelligence in various fields, machine-learning algorithms were developed and are now used in the medical profession. Machine learning or artificial intelligence mimics human function when processing the data [13]. Massive data and essential evidence-based information are mined using machine learning methods to create relevant models. According to Sonia Pereira et al., reports that pregnancy-related factors were used to predict accurate delivery techniques in order to determine how better services can be provided to antenatal

women in order to prevent the anticipated complications. In this study, five machine learning algorithms were used to diagnose the physical condition of the fetus [13].

Prospective studies can be conducted by recruiting women with PIH using the GESTOSIS score's criteria. Three machine-learning algorithms were used to detect preeclampsia early on: Deep Neural Networks (DNN), Logistic Regression (LR), and Support Vector Machine (SVM). The GESTOSIS parameters include maternal biodata, obstetrical characteristics, antenatal lab reports, and ultrasonography. Cross-validation was used to assess the calibration and discrimination under the receiver-operating curve (AUROC).

1.2 Novelty and contribution

According to the authors' review, currently, there hasn't been any research work done by using the GESTOSIS score and machine learning tools to predict pregnancy-induced hypertension. As a result, the current study encourages clinicians and grassroot health care professionals to use this tool to screen pregnant women high-risk for PIH. In addition, in this study, the problem-based learning techniques use machine learning algorithms to understand better prediction models, which are most fit to envisage the PIH accurately. This study will become the first to combine the literature of relevant studies on the GESTOSIS score. The current study guides new researchers to acquire basic skills in other engineering fields. The investigators from the field of Nursing conducted this study in collaboration with experts in engineering fields who had the skills to apply the machine learning predictive models. Machine learning tools are part of engineering, usually done either by coding or without coding.

To explain this study more specifically, tools-based simulation is considered an accurate method for visualizing and analyzing the data without having coding skills. The researchers in this study trained thoroughly with the tools and analysis done with engineering skills. These machine-learning tools are also simple to use for novice researchers and scientists to analyse their data.

In view of the above description, the following are the objectives of the current original study.

- To assess the antenatal women at high risk for prediction of pregnancy induced hypertension (PIH).
- To obtain in depth understanding and evaluate the risk elements by using machine learning models for prediction of pregnancy induced hypertension.
- To assess the efficacy of GESTOSIS score on prediction of pregnancy induced hypertension via machine learning algorithms.
- To comprehend the effect of dataset on the recital of predictive models for pregnancy induced hypertension.

2. RESEARCH DESIGN

We used the purposive sampling technique to enroll 70 antenatal women who had completed 20 weeks of gestational age. This study excluded antenatal women who had already been diagnosed with PIH. The final calculated sample size was 70, based on 10% of the estimated prevalence rate of PIH among all pregnancies at a 95% confidence level and 5% error at the margin.

2.1 Data correlation

Table 1. Significant input attributes with PIH target attribute

| Sr. No. | Attribute | Correlation Coefficient | Association |
|---------|------------------------------|-------------------------|-------------------------|
| 1. | Risk_score_sum | +0.919 | Very strong association |
| 2. | History of PIH | +0.941 | Very strong association |
| 3. | Pre-eclampsia family history | +0.690 | Moderate association |
| 4. | GDM | +0.519 | Moderate association |
| 5. | Chronic Hypertension | +0.317 | Weak Association |

Table 2. Correlation between risk factor score of PIH and maternal demographics

| Parameters | GESTOSIS Score | | Total | Chi-square | p value |
|--------------------------|----------------------|-----------------------|-------|------------|---------|
| | At risk (≥ 3) | Not at risk (< 3) | | | |
| Age in years | | | | | |
| 18 – 25 | 12 | 26 | 38 | 3.82 | 0.01 |
| 26 – 30 | 14 | 15 | 29 | | |
| 31 – 35 | 0 | 3 | 3 | | |
| Gestational age in weeks | | | | | |
| 20 – 25 | 8 | 3 | 11 | 7.36 | 0.04 |
| 26 – 30 | 5 | 12 | 17 | | |
| 31 – 35 | 6 | 16 | 22 | | |
| 36 – 40 | 7 | 13 | 20 | | |

Table 3. Association between target variable (PIH) and other input multi variables

| Sr. No. | Input variables | P value | S value |
|---------|------------------------------------|---------|---------|
| 1 | Risk_Score_Sum | +0.919 | +0.882 |
| 2 | Pre-eclampsia family history | +0.690 | +0.659 |
| 3 | GDM | +0.519 | +0.515 |
| 4 | Women with CAD | +0.372 | +0.398 |
| 5 | Increased weight gain in pregnancy | +0.330 | +0.334 |
| 6 | Chronic Hypertension | +0.317 | +0.302 |
| 7 | Age interval | -0.263 | -0.287 |
| 8 | Below 19 | +0.255 | +0.272 |
| 9 | Dylipidemia | +0.234 | +0.203 |
| 10 | Women with SGA | +0.234 | +0.203 |
| 11 | hypothyroidism | +0.234 | +0.203 |
| 12 | Pregnancy with IVF | +0.223 | +0.247 |
| 13 | Anemia | +0.183 | +0.165 |
| 14 | Primigravida | +0.169 | +0.203 |
| 15 | Pitting oedem | +0.141 | +0.143 |
| 16 | PCOD | +0.129 | +0.129 |
| 17 | Obesity | +0.119 | +0.100 |
| 18 | Above 35 | +0.095 | +0.109 |

Note: P value = Pearson correlation, S value= Spearman correlation

Identifying the correlation between the two variables is imperative to understand the significance between those variables. The values of correlation and chosen variables can affect the predicting tools. The linear relationship between two variables is determined by Pearson Correlations (PC) and Spearman correlations (SC). The correlation coefficient cascades between -1 and +1; -1 indicates a strong negative association among two variables, +1 indicates a robust positive association, while 0 indicates no linear association. A

correlation value of less than 0.3 designates a weak association, while values between 0.3 and 0.7 specify a moderate association. If the value is greater than 0.7, it specifies a sturdy association among two variables [14, 15].

Table 1 depicts the correlation between variables such as family history of Pre-eclampsia, Gestational Diabetes Mellitus (GDM), and Chronic Hypertension. In Table 1, all variables show positive values, which are generated using the Orange tool. Family history of preeclampsia, and GDM show moderate association (+0.690 and +0.519), whereas the previous history of PIH has very strong association.

Table 2 indicated that the age of the pregnant women and gestational age had a significant correlation with the PIH risk score.

Table 3 presented the ‘P’ and ‘S’ values of the target variables of pregnancy-induced hypertension in comparison to the other input multi variables.

2.2 GESTOSIS score scale

Table 4 indicated that GESTOSIS scale consists of 24 items, with scores ranging from 1 to 13 for mild symptoms, and each item has a score of 1. Items from 14–17 are classified as having moderate PIH symptoms, and each item has a score of 2. Items from 20 to 24 are classified as severe PIH symptoms, and each item receives a score of 3. The score is allotted based on the woman's responses and the clinician's assessment.

Table 4. GESTOSIS score for prediction of pregnancy induced hypertension

| Sr. No. | Risk Factors | Score |
|---------|--|-------|
| 1 | Age above 35 years | 1 |
| 2 | Age below 19 years | 1 |
| 3 | Maternal Anemia | 1 |
| 4 | Obesity (BMI >30) | 1 |
| 5 | Pregnant for the first time | 1 |
| 6 | Short duration of sperm exposure | 1 |
| 7 | Woman born as small for gestational age | 1 |
| 8 | Family history of cardiovascular disease | 1 |
| 9 | Polycystic ovary syndrome | 1 |
| 10 | Inter pregnancy interval more than 7 years | 1 |
| 11 | Conceived with Assisted Reproductive (IVF/ ICSI) Treatment | 1 |
| 12 | Chronic vascular disease (Dyslipidemia) | 1 |
| 13 | Excessive weight gain during pregnancy | 1 |
| 14 | Maternal hypothyroidism | 2 |
| 15 | Family history of pre-eclampsia | 2 |
| 16 | Gestational diabetes mellitus | 2 |
| 17 | Obesity (BMI > 35 kg/M2) | 2 |
| 18 | Multifetal pregnancy | 2 |
| 19 | Hypertensive disease during previous pregnancy | 2 |
| 20 | Mental disorders | 3 |
| 21 | Inherited / Acquired Thrombophilia | 3 |
| 22 | Maternal chronic kidney disease | 3 |
| 23 | Autoimmune disease (SLE / APLAS / RA) | 3 |
| 24 | Pregnancy with Assisted Reproductive (OD or Surrogacy) Treatment | 3 |

Pattern of risk scoring

- ✓ At Low risk for prediction of PIH- 1
- ✓ At Moderate risk for prediction of PIH- 2
- ✓ At High risk for prediction of PIH- 3
- ✓ With careful history and assessment of woman, a total score is obtained from time to time.

When the total score is ≥ 3 ; pregnant woman was marked as **‘At risk’**

Professionals translated the GESTOSIS scale from English to Marathi. A native English speaker translated and checked its back. Throughout its conversion, it made subtle philosophical, social strata, theoretical, and dialectal sameness. This scale was pretested on ten antenatal women at Talera Pimpri Chinchwad Municipal Corporation (PCMC) hospital in Pune using interview and assessment methods. Cronbach's alpha was used to assess the reliability of the GESTOSIS score scale, and the value was 0.74, which falls within the acceptable range of reliability. The scale discovered was feasible to administer to pregnant women. Following were the steps involved in the design of the current study.

Step 1: Collection of the data and explanation

The primary data was collected from antenatal women who had completed at least 20 weeks of gestation and visited Yashwantrao Chavan Memorial Hospital (YCM) antenatal OPD. To support the supplementary findings, the researchers revisited these women in the third trimester to validate the data collected in the second trimester. The investigators further re-evaluated the investigations, such as ultra-sonography to evaluate the fetal and placental weight about gestation age. Women who were found to be at high risk for predicting PIH were referred to an expert for further evaluation. This step consists of data processing, feature extraction, and variable correlation analysis.

Step 2: Descriptive statistics

One of the data mining methods involving mathematics and related data collection and elucidation is descriptive statistics for predicting a high PIH data set [16]. The Jeffreys's Amazing Statistics Program is a simple tool to use for researchers with limited computer skills [17].

Table 5 depicts the risk score for pregnancy-induced hypertension which is classified into Low Risk (1), moderate risk (2), and severe risk (3) for the prediction of hypertension in pregnancy based on the antenatal woman's highest score.

Table 5. Categorization of the risk score of the pregnancy induced hypertension

| Risk_Score | Risk_% | Risk_Level | Risk_Level | Participants |
|--------------|--------|------------|---------------|--------------|
| 1 | 3 | | | |
| 2 | 5 | 1 | Low Risk | 43 (61.43) |
| 3 | 8 | | | |
| 4 | 10 | 2 | Moderate Risk | 16 (22.86) |
| 5 | 13 | | | |
| 6 | 16 | | | |
| 7 | 18 | 3 | High Risk | 11 (15.71) |
| 8 | 21 | | | |
| Total | | | | 70 |

Table 6 shows the forty-three women fell under the low-risk criteria for pregnancy-induced hypertension, while the remaining women fell under the moderate and severe-risk criteria category.

The descriptive statistics in Table 7 show that the risk factor for pregnancy-induced hypertension had a higher mean value (PIH). Among the parameters chosen, there were no missing values. Table 7 findings indicate that the primary variables presented in this table are family history of pre-eclampsia,

eclampsia, history of GDM, chronic hypertension, and previous PIH history. The greatest mean (1.543), mode (1.000), and median (1.000) values can be seen in the parameter of previous history of PIH data. The family history of pre-eclampsia has a greater standard deviation (0.827), followed

by the previous history of PIH. The values of the Standard Error of Skewness (0.287) for all chosen parameters are similar. However, the Skewness of PIH history is less apparent. The minimum (1.00) and maximum (3.000) values are higher in PIH.

Table 6. Distribution of the participants based on the different categories for the prediction of pregnancy induced hypertension

| PIH category | Risk score sum | Frequency | Percentage | Cumulative percent |
|-----------------------|----------------|-----------|----------------|--------------------|
| 1 – Low risk category | 1 | 8 | 18.605 | 18.605 |
| | 2 | 18 | 41.860 | 60.465 |
| | 3 | 17 | 39.535 | 100.000 |
| | Missing | 0 | 0.000 | |
| | Total | 43 | 100.000 | |
| 2 – Moderate Risk | 4 | 9 | 56.250 | 56.250 |
| | 5 | 7 | 43.750 | 100.000 |
| | Missing | 0 | 0.000 | |
| | Total | 16 | 100.000 | |
| | 5 | 1 | 9.091 | 9.091 |
| 3 – High risk | 6 | 4 | 36.364 | 45.455 |
| | 7 | 4 | 36.364 | 81.818 |
| | 8 | 2 | 18.182 | 100.000 |
| | Missing | 0 | 0.000 | |
| | Total | 11 | 100.000 | |

Table 7. Descriptive statistics of selected parameters in relation to the total risk score

| Parameters | Risk score sum | Family History of Pre -eclampsia | GDM | Chronic Hypertension | History of PIH |
|------------------------|----------------|----------------------------------|--------|----------------------|----------------|
| Valid | 70 | 70 | 70 | 70 | 70 |
| Missing | 0 | 0 | 0 | 0 | 0 |
| Mean | 3.414 | 0.429 | 0.257 | 0.086 | 1.543 |
| Std. Error of Mean | 0.218 | 0.099 | 0.081 | 0.049 | 0.090 |
| Median | 3.000 | 0.000 | 0.000 | 0.000 | 1.000 |
| Mode | 2.000 | 0.000 | 0.000 | 0.000 | 1.000 |
| Std. Deviation | 1.822 | 0.827 | 0.674 | 0.408 | 0.755 |
| Skewness | 0.778 | 1.423 | 2.268 | 4.614 | 0.993 |
| Std. Error of Skewness | 0.287 | 0.287 | 0.287 | 0.287 | 0.287 |
| Kurtosis | -0.091 | 0.026 | 3.236 | 19.853 | -0.512 |
| Std. Error of Kurtosis | 0.566 | 0.566 | 0.566 | 0.566 | 0.566 |
| Minimum | 1.000 | 0.000 | 0.000 | 0.000 | 1.000 |
| Maximum | 8.000 | 2.000 | 2.000 | 2.000 | 3.000 |
| Sum | 239.000 | 30.000 | 18.000 | 6.000 | 108.000 |
| 25th percentile | 2.000 | 0.000 | 0.000 | 0.000 | 1.000 |
| 50th percentile | 3.000 | 0.000 | 0.000 | 0.000 | 1.000 |
| 70th percentile | 4.750 | 0.000 | 0.000 | 0.000 | 2.000 |

Figure 1 illustrates that the majority of the samples had a score between 1 and 5, with a mean value of 3. As a result, 61% of antenatal women are at low risk for PIH. Figure 2 to Figure 4 show that the majority of participants have no family history of preeclampsia, gestational diabetes, or chronic hypertension. Figure 5 depicts that majority (61.43%) of the participants fall under the risk level of 1 (Low Risk), and 16% of women with a history of preeclampsia are at high risk for PIH. Figure 6 reveals that 61%, 23%, and 16% of prenatal women fall into the low risk, moderate risk, and high risk groups for PIH, respectively.

Step 3: Development of the prediction models

The data was normalized for pre-processing, and correlation method was used to find the significant attributes in the data set. Total features are further classified into three types: independent attributes, dependent attributes, and meta attributes using Orange software, as shown in Figure 7.

Figure 8 and Figure 9 illustrated that a family history of PIH and a previous history of pre-eclampsia predicted susceptibility to pregnancy-induced hypertension.

Step 4: Evaluation of prediction model's performance

The Orange model was used to select nine algorithms, including Support Vector Machine (SVM), Stochastic Gradient Descent (SGD), Multi-layer Perceptron (MLP), k-Nearest Neighbors (kNN), Multiple Linear Regression (MLR), Decision Tree (DT), Gradient Boosting (GB), Random Forest (RF), and Adaptive Boosting (AB) as shown in Figure 10. The prediction models are created using the input data set and fine-tuning each algorithm's hyperparameter. After clicking on each algorithm, we can fine-tune the hyperparameters to maintain better prediction accuracy. To develop prediction models, 20-fold cross validation model is adopted.

This step helps in predicting the performance of predicting models with the available dataset. The parameters of the performance matrix are as follows; Mean Square Error (MSE), Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and coefficient of determination (R^2) [18].

Table 8 depicts the tuned hyperparameter for both classification, and regression prediction model. AB algorithm performs better predictive results with the hyperparameter namely learning rate (0.50000), classifier algorithm (SAMME.R), and regression loss (Linear).

| | Learning rate | 0.50000 |
| | Classification algorithms | SAMME.R |
| | Regression loss function | Linear |

metrics are namely Precision, Recall, F-Measure, Accuracy, and RMSE [18].

Table 13 and Table 14 show similar prediction performance results based on regression and classification prediction models, respectively. In both prediction models, the AB

algorithm performed better, with an accuracy of 97% to 99% in predicting PIH. The MLR prediction model, on the other hand, is only relevant in the regression prediction model.

Table 13. Performance of individual algorithms based regression prediction

| Sr. No. | Algorithm | MSE | RMSE | MAE | R ² |
|---------|-----------|--------------|--------------|--------------|----------------|
| 1 | SVM | 0.165 | 0.407 | 0.334 | 0.706 |
| 2 | SGD | 0.147 | 0.383 | 0.308 | 0.739 |
| 3 | MLP | 0.130 | 0.360 | 0.271 | 0.769 |

(a) Target 1 classifier for Low Risk of PIH

(b) Target 2 classifier for Moderate risk of PIH

(c) Target 3 classifier for High Risk of PIH

Figure 11. Different models ROC curve-based classification prediction evaluation

Evaluating the ROC curve (Figure 11) and the area under the ROC curve (Table 13 and Table 14) for the algorithms run in the second stage of modelling revealed that the AB algorithm shows better prediction results in all PIH targets.

3.1 Discussion

Leelavathi et al. studied the efficacy of Uterine Artery Doppler Ultrasonography and the roll-over test in predicting pregnancy-induced hypertension. The antenatal women were screened with Doppler artery ultrasonography at the gestational age of eleven to thirteen weeks. The women were followed up at twenty-one to twenty-four weeks, and the roll-

over test was performed at twenty-eight to thirty-two weeks to see if they were at high risk for pre-eclampsia and eclampsia [19]. In the current study, 37.1% of women were at high risk for pregnancy-induced hypertension. Blood pressure, mean arterial pressure (MAP), platelet count, and urine albumin tests were performed on these 26 women. About 53.8% (14) of women were significantly at high risk for hypertension prediction. In detail, approximately 92.31% of women had blood pressure levels higher than 140/90 mmHg.

Antenatal women with a positive roll-over test possess a significantly higher risk of having a small gestational age baby. It was confirmed during their antenatal check-ups by

ultrasonography and examination of pre-pregnancy and pregnancy weight gain. Women who weigh fifty kilograms or less and gain less than ten kilograms during pregnancy or who have a weight gain disparity of 20% or less, pose a significant risk for developing Small for Gestational Age (SGA) fetus [20]. Women with a positive GESTOSIS score had a significantly high SGA fetus in the current study, a mean arterial pressure greater than 100 mmHg, and elevated urine albumin levels. About 30% of women's placental and fetal weights were not correlated with gestational age; they were observed to be lower than expected values.

However, previous research conducted by Kaypour et al. [21], they concluded that the roll-over test alone cannot predict pregnancy-induced hypertension but if this test is combined it with other predictive tools such as Doppler artery ultrasonography and the GESTOSIS score can provide more accurate results in predicting hypertensive diseases in pregnancy. According to Andersen [22], single tools, such as the roll-over test, are insufficiently sensitive and specific as a screening test. Finally, Marshall and Newman [23] suggested that roll-over tests be combined with other predictive tools to achieve more positive results.

Sufriyana et al. looked into validating an artificial intelligence (AI) tool for predicting pregnancy-induced hypertension. The data set includes 95 personal characteristics and the medical history of pregnant women. Six algorithms for comparison were created by automating the receiver operating characteristics curve (AUROC). This economic model was primarily used to predict PIH [24]. The predictive analytics software acts as an artificial intelligence in obstetrics, assisting in diagnosing preeclampsia. Machine learning algorithms will aid in improving the accuracy of preeclampsia risk calculation in pregnant women [25].

The Expert System for Preeclampsia Prevention Program (ESPPP) is used to detect pregnancy-induced hypertension. This program uses pragmatic criteria to diagnose and recommend treatment for PIH [26]. Marin I et al. used a non-invasive technique to detect the presence of preeclampsia.

The blood pressure is measured using an i-bracelet Eurostars smart bracelet, an "Intelligent bracelet for blood pressure monitoring and detection of preeclampsia." Every pregnant woman's age, weight, and blood pressure measurements are used as input data. A series of hidden states comprised the prediction model [27]. Zhang X et al. studied the relationship between blood data characteristics of antenatal women in severe PIH [28].

According to a retrospective study, uric acid, erythrocyte haemoglobin concentration, globulin, platelet distribution width, potassium ion, age, family history of hypertension, systolic blood pressure, diastolic blood pressure, pulse, and gestational age greater than 34 weeks were independent risk factors for prediction of preeclampsia. The optimal Light 5 GBM algorithm parameters were discovered using a 5-fold cross-validation algorithm after screening these independent risk factors using univariate analysis and logistic regression analysis. The preeclampsia prediction model based on the Light GBM machine learning algorithm has a higher prediction effect for prediction of PIH [29].

4. CONCLUSIONS

Today, there are numerous diagnostic methods available to detect hypertensive pregnancy disorders. However, they

are not always available to pregnant women, especially in sub-centers and primary health care centers. The GESTOSIS score is a simple predictive tool that all front-line health care workers can use. Preeclampsia can be predicted early on, and pregnant women can receive definitive treatment at the appropriate time to reduce the negative outcome of the pregnancy. The GESTOSIS score scale can be used in primi and multipara mothers with a history of PIH. The GESTOSIS score is endorsed by the Federation of Obstetrics and Gynecological Society in India (FOGSI). This tool is considered a low-cost alternative to other tests and simultaneously ensures the efficacy of the test. It is a simple, cost-effective, and economic scale that can be employed during the initial assessment of all antenatal women to predict the risk of pregnancy-induced hypertension. Based on the parameters of the GESTOSIS score scale, various machine learning algorithms can be employed to predict preeclampsia.

This study provides information regarding the associating factors responsible for predicting pregnancy-induced hypertension. Early prediction helps to provide accurate treatment to pregnant women at the right time. In this study, it is attested that the adoption of data mining techniques on the medical data has a large scope for diagnosis and prediction of diseases that indicates the medical professionals to provide the preliminary care for life-threatening disease conditions. Data mining techniques help in enhancing care and maximizing salvage rates. In this article, various prediction machine-learning algorithms are deployed on medical data sets to understand the risk factors responsible for causing PIH. This study recommends that future researchers apply a sequential model to this data set, including a recursive deep neural network that increases the accuracy levels in predicting PIH. This study concludes to state that provided factors comprised in the GESTOSIS score optimally can be used on the optimal dataset for the prediction of PIH.

ACKNOWLEDGMENT

The researchers have been continuously supported by the management of Symbiosis College of Nursing and Symbiosis International (Deemed University) (SIU) and administration YCM hospitals, and the participants for this study.
